

Professional Demo Script

AI-Powered Customer Support Ticket Triage

SaaS Delivery Simulation for Customer Experience Operations

Prepared by	Jagriti Banerjee
Document Type	Demo Script and Walkthrough Plan
Project Context	Independent portfolio simulation for AI-enabled SaaS delivery
Mock Client	UrbanCart - E-commerce customer support operations
Primary Focus	Requirements understanding, demo flow, stakeholder communication, training readiness, and implementation support

This document presents a professional client-facing demonstration script for a simulated AI-enabled SaaS workflow. It is designed to show how customer support tickets can be classified, prioritized, and routed through a structured delivery approach without using real client data or production AI systems.

1. Executive Demo Overview

This demo script supports a SaaS delivery simulation for an AI-powered customer support ticket triage workflow. The objective is to communicate the business problem, proposed solution, workflow logic, expected operational value, and handover approach in a professional and client-ready manner.

The demo is structured for a mixed audience that may include business stakeholders, support leaders, product teams, technology teams, and implementation teams. The script avoids unnecessary technical depth while still explaining how the workflow supports business efficiency and customer experience outcomes.

1.1 Demo Objective

- Explain the business challenge created by manual ticket review and routing.
- Demonstrate how an AI-enabled SaaS workflow can classify tickets by category and urgency.
- Show how routing logic can help internal support teams respond faster and more consistently.
- Highlight delivery documents such as BRD, PRD, user stories, implementation plan, training guide, and sample data.
- Position the project as a realistic implementation-support exercise for an entry-level AI delivery role.

1.2 Demo Audience

Audience	What they care about	How the demo addresses it
Business stakeholders	Efficiency, customer experience, escalation visibility	Shows faster routing, prioritization, and operational clarity
Support managers	Ticket volume, workload distribution, urgent-case visibility	Explains categories, priority rules, and team assignment
Product team	Feature scope, user flow, edge cases	Connects requirements to product behavior and acceptance criteria
Technology team	Logic, data inputs, routing rules, integration considerations	Explains classification structure and workflow dependencies
Implementation team	Delivery readiness, handover, training, open questions	Shows documents, assumptions, risks, and training material

2. Recommended Demo Flow

The demo should be delivered as a short, structured walkthrough. A strong delivery flow moves from business problem to proposed solution, then into the workflow example, business value, limitations, and next steps.

Section	Approx. duration	Purpose
Opening and context	45 seconds	Introduce the project, role of the demo, and simulated client context
Business problem	60 seconds	Explain why manual support triage is inefficient
Proposed SaaS workflow	90 seconds	Show the AI-enabled ticket classification, priority, and routing flow
Example ticket walkthrough	2 minutes	Demonstrate one high-impact ticket from intake to routing
Delivery documentation	60 seconds	Present BRD, PRD, user stories, implementation plan, demo script, and training guide
Risks and controls	45 seconds	Explain manual review, assumptions, and responsible implementation boundaries
Closing and value summary	45 seconds	Summarize business value and delivery readiness

3. Opening Script

Use this opening to create a professional first impression and set the scope clearly.

Spoken Script:

Hello, my name is Jagriti Banerjee. This project is a SaaS delivery simulation for an AI-powered customer support ticket triage workflow. The goal is to demonstrate how a customer experience platform can help a mock e-commerce client reduce manual ticket sorting, improve response consistency, and route urgent customer issues to the correct team faster.

The project focuses on delivery readiness rather than production AI development. I prepared structured documentation including a BRD, PRD, user stories, implementation plan, demo script, training guide, and sample ticket dataset to show how business requirements can be converted into an implementation-ready workflow.

4. Business Problem Narrative

This section explains the pain point from the client perspective. It should be simple enough for non-technical stakeholders and specific enough for product and technology teams.

Spoken Script:

The mock client, UrbanCart, receives a high volume of customer support tickets across issues such as refunds, delivery delays, payment failures, cancellations, damaged products, login issues, and general queries. In the current manual process, support agents must read every message, identify the issue type, decide urgency, and route it to the correct team.

This creates four major problems. First, first-response time becomes slower. Second, ticket categorization becomes inconsistent across agents. Third, urgent tickets such as payment failures or repeated complaints may not be escalated quickly. Fourth, support managers do not get a clean operational view of ticket types and priority levels.

4.1 Problem-to-Impact Mapping

Current issue	Operational impact	Customer experience impact
Manual ticket reading	Higher agent workload and slower triage	Delayed first response
Inconsistent categorization	Reporting becomes unreliable	Customers may receive incorrect support path
No automated priority flag	Urgent cases can be missed	High-friction issues escalate
Manual routing	Ticket ownership delays	Resolution time increases
Limited visibility	Managers lack structured insights	Recurring issues remain hidden

5. Proposed SaaS Solution Narrative

This section positions the solution as a SaaS workflow that supports customer support operations. The language should stay honest: this is a simulation and the classification is represented through explainable workflow logic.

Spoken Script:

The proposed solution is an AI-enabled SaaS workflow that assists ticket triage. When a customer submits a ticket, the workflow reads the ticket text, identifies the likely issue category, assigns a priority level, and routes the ticket to the appropriate team. The output helps support agents act faster while giving managers better visibility into urgent issues and recurring ticket categories.

For this simulation, the AI behavior is represented through explainable category and priority rules. In a real implementation, these rules could be enhanced using a trained model, natural language processing, client-specific workflows, and continuous feedback from support teams.

5.1 Workflow Logic

Input	Processing step	Output
Customer ticket message	Identify intent and issue keywords	Ticket category
Ticket category and urgency words	Apply priority rules	High, Medium, or Low priority
Category and priority	Apply routing map	Assigned support team
Unclear or low-confidence ticket	Manual review rule	Manual review flag

6. Detailed Demo Walkthrough

This is the main walkthrough that should be used during the demo. The presenter can show the sample CSV, the documentation repository, and the workflow diagram while speaking through these steps.

Step 1 - Ticket Intake

A customer submits a support ticket through the support portal, email, chat, or integrated helpdesk channel. The ticket enters the SaaS customer support platform as a text-based customer message.

Step 2 - AI-Assisted Classification

The workflow reviews the message and identifies the most relevant issue category. Categories include Refund, Delivery Delay, Payment Issue, Damaged Product, Cancellation, Login Issue, and General Query.

Step 3 - Priority Assignment

The workflow assigns priority based on issue type and urgency. Payment failures, repeated complaints, damaged products, and escalation language are treated as higher priority than general queries.

Step 4 - Team Routing

The ticket is routed to the relevant support team such as Payments Team, Billing and Refund Team, Logistics Team, Returns and Replacement Team, Order Management Team, Technical Support Team, or General Support Team.

Step 5 - Agent Review

The support agent reviews the assigned category, priority, and routing team. If the classification appears incorrect, the agent can move the ticket to manual review.

Step 6 - Manager Visibility

Support managers can track high-priority tickets, volume by category, manual-review queues, and recurring customer issues to improve support operations.

7. Example Ticket Walkthrough

Use one realistic ticket example to make the workflow clear and memorable.

Spoken Script:

Let us take one sample ticket: "My payment was deducted but the order was not placed. Please help urgently."

The workflow identifies this as a Payment Issue because the customer mentions payment deduction and failed order placement. It assigns High Priority because money has been deducted and the customer uses urgent language. The ticket is then routed to the Payments Team so the issue can be investigated by the correct team without unnecessary manual sorting.

Field	Demo output
Customer message	My payment was deducted but the order was not placed. Please help urgently.

Detected category	Payment Issue
Priority	High
Routing team	Payments Team
Reasoning	Payment deduction and urgent wording indicate a high-impact customer issue
Suggested next action	Payments Team verifies transaction status and updates the customer

8. Ticket Category and Routing Matrix

This matrix should be shown during the demo to demonstrate that the workflow is structured and implementation-ready.

Ticket category	Typical customer message	Default priority	Routing team
Refund	I want to know the status of my refund.	Medium	Billing and Refund Team
Delivery Delay	My order has not arrived yet.	Medium	Logistics Team
Payment Issue	Money was deducted but order was not placed.	High	Payments Team
Damaged Product	The item arrived broken.	High	Returns and Replacement Team
Cancellation	I want to cancel my order.	Medium	Order Management Team
Login Issue	I cannot access my account.	Low	Technical Support Team
General Query	Where can I update my address?	Low	General Support Team

9. Delivery Documentation Walkthrough

This section connects the demo to the role requirements. It shows how a delivery trainee can support product, technology, support, and customer success teams through structured documentation.

Document	Purpose	Delivery value
BRD	Captures business problem, objectives, scope, stakeholders, and success metrics	Aligns business stakeholders before implementation
PRD	Defines functional requirements, non-functional requirements, workflow rules, and user flow	Helps product and technology teams understand expected behavior
User Stories	Translates requirements into role-based user needs and acceptance criteria	Supports Agile-style execution and validation
Implementation Plan	Breaks project into delivery phases and handover steps	Supports structured execution and task follow-up
Demo Script	Provides a consistent explanation for the client-facing walkthrough	Improves demo readiness and communication clarity
Training Guide	Explains categories, priorities, and user instructions	Supports user adoption and onboarding
Sample Data	Provides realistic test tickets for demonstration	Helps validate workflow logic

10. Client-Facing Communication Points

The presenter should emphasize practical business value and avoid overclaiming. This is especially important because the project is a simulation and not a production implementation.

Key statements to use:

- This is an independent portfolio simulation designed to demonstrate AI delivery and SaaS implementation understanding.
- The project does not use real customer data and does not represent a live client implementation.
- The classification logic is represented through explainable workflow rules for demo purposes.
- The main focus is on requirement documentation, implementation planning, demo readiness, and training support.
- In a real client environment, the workflow would require discovery sessions, data review, integration planning, testing, user acceptance, and feedback loops.

11. Risks, Controls, and Responsible Boundaries

A professional demo should include limitations and controls. This shows maturity and delivery awareness.

Risk	Possible impact	Control or mitigation
Incorrect ticket classification	Ticket may be routed to the wrong team	Manual review flag and agent override option
Unclear customer message	Low classification confidence	Route to General Support or Manual Review queue
Priority misassignment	Urgent issue may be delayed	Define high-priority triggers and escalation rules
Client-specific workflow variation	Standard rules may not match client process	Conduct discovery and customize categories/routing
Overreliance on automation	Agents may stop validating outputs	Train agents to review and correct outputs
Data privacy concerns	Sensitive data exposure risk	Use anonymized data and define data handling controls

12. Closing Script

Spoken Script:

To summarize, this project demonstrates how an AI-enabled SaaS workflow can support customer experience operations by reducing manual ticket sorting, improving prioritization, and routing customer issues to the correct teams more consistently.

From a delivery perspective, I focused on the complete implementation support layer: understanding the business problem, documenting requirements through BRD and PRD formats, writing user stories and acceptance criteria, preparing an implementation plan, creating a demo script, and building a training guide. This helped me understand how business, product, technology, support, and customer success teams can work together to deliver an AI-enabled customer support workflow.

13. Interview Talking Points

If asked to explain the project in an interview, the following version can be used as a concise response.

60-second explanation:

I created an AI-powered customer support ticket triage simulation to understand SaaS implementation and AI delivery from a business and documentation perspective. The mock client is an e-commerce company receiving tickets for refunds, delivery delays, payment failures, damaged products, cancellations, login issues, and general queries. I prepared the BRD, PRD, user stories, implementation plan, demo script, training guide, and sample ticket dataset. The workflow classifies tickets, assigns priority, and routes them to the correct support team. The project is not a live client implementation; it is a portfolio simulation designed to show requirement understanding, structured documentation, demo preparation, and delivery support readiness.

14. Appendix: Demo Checklist

Checklist item	Status
Explain mock client and business problem	Prepared
Show customer ticket categories	Prepared
Walk through payment issue example	Prepared
Explain priority and routing logic	Prepared
Present delivery documents	Prepared
Mention assumptions and limitations	Prepared
Close with business value and delivery learning	Prepared

15. Professional Disclaimer

This document is an independent academic and portfolio simulation prepared by Jagriti Banerjee. It does not represent a live deployment, a real client implementation, or production AI model training. No real customer data is used. The purpose is to demonstrate structured thinking, SaaS delivery understanding, requirement documentation, demo communication, training readiness, and implementation support capability.
